Abstract

$C_{26}H_{22}ClFN_2O_5Sn$, triclinic, $P\bar{1}$ (no. 2), $a = 7.1473(6)$ Å, $b = 12.8246(11)$ Å, $c = 13.2899(11)$ Å, $\alpha = 97.541(5)^\circ$, $\beta = 94.503(6)^\circ$, $\gamma = 96.247(5)^\circ$, $V = 1195.13(18)$ Å³, $Z = 2$, $R_{gt}(F) = 0.0325$, $wR_{ref}(F^2) = 0.0756$, $T = 296(2)$ K.

CCDC no.: 1952923

The molecular structure is shown in the figure. Table 1 contains crystallographic data and Table 2 contains the list of the atoms including atomic coordinates and displacement parameters.

Source of material

The melting point of the compound was measured on a Mel-temp II digital melting point apparatus and was uncorrected. The IR spectrum was recorded on a Perkin-Elmer RX1 spectrophotometer as a Nujol mull in a KBr cell from 4000 to 400 cm⁻¹. The ¹H NMR spectrum was recorded in DMSO-d₆ solution on a Jeol JNM-ECA 400 MHz NMR spectrometer with chemical shifts relative to tetramethylsilane.

(E)-N'-(1-(4-Methoxy-2-hydroxybenzylidene)-3-hydroxy-2-naphthohydrazide was synthesised from 4-methoxy-2-hydroxybenzaldehyde (Merck) and 3-hydroxy-2-naphthoic hydrazide (Sigma Aldrich) in a 1:1 molar ratio. Di(4-fluorobenzyl)tin dichloride was synthesised by the direct reaction of 4-fluorobenzyl chloride (Merck) and metallic tin powder (Merck) in toluene according to a literature procedure [5]. Di(4-fluorobenzyl)tin dichloride (0.41 g, 1 mmol) and (E)-N'-(1-(4-methoxy-2-hydroxybenzylidene)-3-hydroxy-2-naphthohydrazide (0.34 g, 1 mmol) were dissolved in methanol (25 mL) and refluxed for 3 h. After filtration, the filtrate was evaporated slowly until yellow crystals formed. The crystals were filtered, washed with a minimum amount of methanol-ethanol and air-dried. Yield: 0.10 g (16%). M.pt: 433–435 K. IR (cm⁻¹): 3391 (br) v(O—H), 1638 v(C=N), 1603 v(C=N—N=C), 1032 v(C—O), 466 v(Sn—O). ¹H NMR (DMSO-d₆, δ (ppm)): δ 2.80 (s, 2H, CH₂), 3.45 (s, 2H, OH₂), 3.88 (s, 3H, OCH₃), 6.70 (d, 1H, $J = 8.80$ Hz, Ph-H), 7.28–7.45 (m, 4H, Ph-H), 7.50–7.66 (m, 4H, Ph-H), 7.73–7.84 (m, 3H, Ph-H), 8.50 (s, 1H, Ph-H), 8.58 (s, 1H, CH), 11.58 (s, 1H, OH).

Experimental details

The C-bound H atoms were geometrically placed (C—H = 0.93–0.97 Å) and refined as riding with $U_{iso}(H) = 1.2\text{--}1.5U_{eq}(C)$. The O-bound H-atoms were located in a difference Fourier map but were refined with a distance restraint O—H = 0.82 ± 0.01 Å, and with $U_{iso}(H)$ set to $1.5U_{eq}(O)$. Owing to poor agreement, four reflections, i.e. (7 –5 6), (–1 –7 15), (–1 –7 16) and (1 –6 3), were omitted from the final cycles of refinement.

Comment

Organotin compounds have been long-known as potential chemotherapeutic agents for the treatment of a variety of cancers [6]. In this context, molecules related to the title organotin compound with a tridentate hydrazone ligand, have been screened for biological activity [7–9]. In continuation of these and structural studies of these organotin hydrazone species [10–13], the title compound, (I), was investigated by X-ray crystallography.

The molecular structure of (I) is shown in the figure (70% displacement ellipsoids). The tin atom is coordinated by the di-negative, tridentate ligand, *via* the oxide-O1, phenoxide-O3 and imine-N2 atoms, a chlorido ligand, a methylene-carbon atom of the organic substituent and a water ligand. The resultant coordination geometry is based on an octahedron with the three *trans* angles deviating significantly from the ideal 180° angle: O1–Sn–O3 = 156.75(7)°, N2–Sn–C20 = 171.06(9)° and Cl1–Sn–O1w = 174.40(5)°. The O,N,O donor atoms of the tridentate ligand occupy meridional positions in the octahedral environment. Deviations are largely related to the acute chelate angles formed in the five-membered, O1–Sn–N2 = 74.21(8)°, and six-membered, O3–Sn–N2 = 84.92(8)°, rings. The Sn–O3(phenoxide) bond length [2.0419(18) Å] is considerably shorter than the Sn–O1(oxide) distance [2.1117(18) Å] and this difference is reflected in the associated C1–O1 [1.306(3) Å] and C14–O3 [1.334(3) Å] bond lengths. Considering the bonding character over the O1–C1–N1–N2–C12 chromophore, the C1–N1 bond [1.315(3) Å] is comparatively short and is only marginally longer than the formally C12–N2 imine bond [1.304(3) Å]. These observations suggest considerable delocalisation of π-electron density over this chromophore; the Sn–Cl1, Sn–N2, Sn–C20 and Sn–O1w bond lengths are 2.4770(7), 2.148(2), 2.143(3) and 2.266(2) Å, respectively. The five-membered chelate ring is planar with the r.m.s. deviation of the five fitted atoms being 0.011 Å. By contrast, the six-membered ring is best described as having an envelope conformation with the O3 atom lying 0.196(3) Å out of the plane defined by the remaining five atoms [r.m.s. deviation = 0.052 Å]; the r.m.s. deviation of the six atoms comprising the chelate ring = 0.075 Å. The dihedral angle between the best planes through the chelate rings is 6.15(8)°, indicating that the rings are almost co-planar. The dihedral angle between the five-membered ring and the least-squares plane through the appended naphthyl ring = 9.30(9)°, a relationship that allows for the formation of an intramolecular hydroxyl-O–H···N(hydrazone) hydrogen bond [O2–H2o···N1: H2o···N1 = 1.78(2) Å, O2···N1 = 2.543(3) Å with angle at H2o = 154(2)°]. The dihedral angle between the six-membered ring and attached phenyl ring is 3.55(9)°, also consistent with a co-planar relationship. Finally, the dihedral

angle between each of the best planes through the five-and six-membered chelate rings and that through the benzyl ring are 58.57(8) and 62.36(8) $^{\circ}$, respectively, indicating a splayed disposition.

The presence of a N,O,O tridentate ligand, with the pendent hydroxy group as in (I), with tin bound to chloride, an organic substituent and a water molecule is a rare structural motif, being observed once previously, namely in aqua-(*n*-butyl)-chlorido-(2-hydroxy-*N*-(2-oxy-3-methoxybenzylidene)benzenecarbohydrazonato)tin(IV), isolated as an ethanol solvate [14].

The most prominent supramolecular contacts in the molecular packing are aqua-O—H \cdots Cl [O1w—H1w \cdots Clⁱ: H1w \cdots Clⁱ = 2.47(2) Å, O1w \cdots Clⁱ = 3.265(2) Å with angle at H1w = 167(3) $^{\circ}$ for symmetry operation (i) 1 + x , y , z] and aqua-O—H \cdots O(hydroxy) [O1w—H2w \cdots O2ⁱⁱ: H2w \cdots O2ⁱⁱ = 1.85(2) Å, O1w \cdots O2ⁱⁱ = 2.657(3) Å with angle at H2w = 174(2) $^{\circ}$ for (ii) 1 - x , 1 - y , 1 - z]. These combine to give rise to a double chain, with a linear topology along the α -axis. The phenyl ring of the benzyl substituent is folded towards the water molecule and shields the water-oxygen atom from participating in an additional (acceptor) hydrogen bonding interaction. The chains are linked into a double layer in the *ab*-plane by very weak methyl-C—H \cdots F interactions [C19—H19a \cdots F1ⁱⁱⁱ: H19a \cdots F1ⁱⁱⁱ = 2.45 Å, C19 \cdots F1ⁱⁱⁱ = 3.374(4) Å with angle at H19a = 161 $^{\circ}$ for (iii) 1 - x , - y , 1 - z]. While there are $\pi\cdots\pi$ stacking and C—H \cdots π interactions apparent in the packing, these occur within the layers, which stack along the *c*-axis direction without directional interactions between them.

To analyse the molecular packing further, an analysis of the calculated Hirshfeld surfaces along with two-dimensional (overall and delineated) fingerprint plots ensued, using Crystal Explorer 17 [15] following standard procedures [16]. The most dominant contacts contributing to the surface are those involving hydrogen, accounting for nearly 90% of all contacts. Important contributions come from C \cdots H/H \cdots C [23.5%], O \cdots H/H \cdots O [11.4%], Cl \cdots H/H \cdots Cl [9.8%] and F \cdots H/H \cdots F [7.8%] contacts but, the prevalent contacts are of the type H \cdots H [35.9%]. The next most important contacts are of the type O \cdots C/C \cdots O [2.6%].
