## Abstract

C<sub>36</sub>H<sub>58</sub>Cd<sub>2</sub>N<sub>6</sub>O<sub>4</sub>S<sub>8</sub>, monoclinic, P2<sub>1</sub>/c (no. 14),  $a = 7.82927(4)$  Å,  $b = 11.64209(5)$  Å,  $c = 26.2493(1)$  Å,  $\beta = 95.6985(4)$ °,  $V = 2380.775(18)$  Å<sup>3</sup>,  $Z = 2$ ,  $R_{\text{gt}}(F) = 0.0158$ ,  $wR_{\text{ref}}(F^2) = 0.0411$ ,  $T = 100(2)$  K.

CCDC no.: 2020556

The molecular structure is shown in the figure. Table 1 contains crystallographic data and Table 2 contains the list

**Table 1:** Data collection and handling.

Crystal:	Colourless prism
Size:	0.09 × 0.07 × 0.06 mm
Wavelength:	Cu K $\alpha$ radiation (1.54184 Å)
$\mu$ :	10.8 mm <sup>-1</sup>
Diffractometer, scan mode:	XtaLAB Synergy, $\omega$
$\theta_{\text{max}}$ , completeness:	67.0°, >99%
$N(hkl)_{\text{measured}}$ , $N(hkl)_{\text{unique}}$ , $R_{\text{int}}$ :	54794, 4261, 0.035
Criterion for $I_{\text{obs}}$ , $N(hkl)_{\text{gt}}$ :	$I_{\text{obs}} > 2 \sigma(I_{\text{obs}})$ , 4150
$N(\text{param})_{\text{refined}}$ :	263
Programs:	CrysAlis <sup>PRO</sup> [1], SHELX [2, 3], WinGX/ORTEP [4]

**Table 2:** Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters (Å<sup>2</sup>).

of the atoms including atomic coordinates and displacement parameters.

### Source of material

Cd[S<sub>2</sub>CN(iPr)CH<sub>2</sub>CH<sub>2</sub>OH]<sub>2</sub> [5] (0.235 g, 0.5 mmol) in acetonitrile (3 mL) and 1,2-di(4-pyridyl)ethylene (Sigma Aldrich; 0.091 g, 0.5 mmol) in acetonitrile (3 mL) were added to a wide neck 10 mL vial equipped with a magnetic stirring bar, and subject to microwave heating on an Anton Paar Monowave 450 with the following parameters: spinning rate = 1000 rpm, ramp from room temperature to 70 °C in 30 mins, holding for 2 h, followed by cooling to 60 °C and left for slow evaporation at room temperature; crystals formed after 3 weeks.

Yield: 0.171 g (61%, based on Cd). **M. pt** (Stuart melting point apparatus SMP30): 466–467 K. **<sup>1</sup>H NMR** (Bruker Ascend 400 MHz NMR spectrometer with chemical shifts relative to tetramethylsilane in CDCl<sub>3</sub> solution at 298 K, ppm): δ 8.70 (dd, 4H, aryl-NCH, <sup>2</sup>J<sub>HH</sub> = 6.20 Hz, <sup>4</sup>J<sub>HH</sub> = 3.00 Hz), 7.44 (dd, 4H, aryl-CCH, <sup>2</sup>J<sub>HH</sub> = 6.24 Hz, <sup>4</sup>J<sub>HH</sub> = 3.04 Hz), 7.24 (s, 2H, =CH), 8.70 (sept, 4H, NCH, J<sub>HH</sub> = 6.20 Hz), 4.02–3.95 (m, br, 16H, CH<sub>2</sub>), 2.44 (s, br, 4H, OH), 1.28 (d, 24H, CH<sub>3</sub>, J<sub>HH</sub> = 6.70 Hz). **<sup>13</sup>C{<sup>1</sup>H} NMR** (as for <sup>1</sup>H NMR): δ 204.9 (S<sub>2</sub>C),

150.4 (aryl-Cq), 143.7 (aryl-CNC), 130.7 (=CH), 121.4 (aryl-CCC), 60.9 (OCH<sub>2</sub>), 58.0 (NCH<sub>2</sub>), 51.0 (NCH), 20.3 (CH<sub>3</sub>).

### Experimental details

The carbon-bound H-atoms were placed in calculated positions (C—H = 0.95–1.00 Å) and were included in the refinement in the riding model approximation, with  $U_{\text{iso}}(\text{H})$  set to 1.2–1.5  $U_{\text{eq}}(\text{C})$ . The O-bound H atoms were refined with O—H = 0.84 ± 0.01 Å and with  $U_{\text{iso}}(\text{H}) = 1.5 U_{\text{eq}}(\text{O})$ .

### Comment

In common with most cadmium dithiocarbamate, Cd(S<sub>2</sub>CNRR')<sub>2</sub>, structures [6], the species with R = isopropyl and R' = CH<sub>2</sub>CH<sub>2</sub>OH is known to associate into a dimer formulated as [Cd(S<sub>2</sub>CN(iPr)CH<sub>2</sub>CH<sub>2</sub>OH)]<sub>2</sub> as a result of equal numbers of tridentate-μ<sub>2</sub>- and chelating-dithiocarbamate ligands leading to five-coordinate Cd centres [5, 7]. However, a kinetic form has also been characterised for this compound [5, 7] which is a rare example of a one-dimensional coordination polymer for cadmium dithiocarbamates [5–8]. Experiments show the polymers to convert to the dimeric form with the egress of time. It is now well established [9] that the addition of potentially bridging bi-pyridyl type molecules (NN) will disrupt the above self-association to form one-dimensional coordination polymers in the case of 1:1 adducts, i.e. {Cd(S<sub>2</sub>CNRR')<sub>2</sub>(NN)}<sub>n</sub> or zero-dimensional adducts when 2:1 species are formed, i.e. {Cd(S<sub>2</sub>CNRR')<sub>2</sub>}<sub>2</sub>(NN); NN is μ<sub>2</sub>-bridging in each case. However, when NN is added to [Cd(S<sub>2</sub>CN(iPr)CH<sub>2</sub>CH<sub>2</sub>OH)]<sub>2</sub>, unpredictable crystallisation outcomes occur, possibly owing to the intervention of hydrogen bonding. Thus, for example, with the classic example of NN, namely 4,4'-bipyridyl, a [Cd(S<sub>2</sub>CN(iPr)CH<sub>2</sub>CH<sub>2</sub>OH)]<sub>2</sub>(4,4'-bipyridyl) species is isolated, i.e. with monodentate and non-coordinating 4,4'-bipyridyl [10]. Monodentate coordination is also found for NN in {[Cd(S<sub>2</sub>CN(iPr)CH<sub>2</sub>CH<sub>2</sub>OH)]<sub>2</sub>}<sub>2</sub>(3-pyridinealdazine)<sub>2</sub> where the dimeric core of {[Cd(S<sub>2</sub>CN(iPr)CH<sub>2</sub>CH<sub>2</sub>OH)]<sub>2</sub>}<sub>2</sub> is retained but, capped by two NN molecules [11]. In a structure closely related to the title compound, formulated as {[Cd(S<sub>2</sub>CN(iPr)CH<sub>2</sub>CH<sub>2</sub>OH)]<sub>2</sub>}<sub>2</sub>[1,2-di(4-pyridyl)ethylene]<sub>3</sub>, one of the NN ligands is bidentate bridging while the others are terminal, monodentate [12]. In continuation of these studies, the crystal structure determination of the title compound, {[Cd(S<sub>2</sub>CN(iPr)CH<sub>2</sub>CH<sub>2</sub>OH)]<sub>2</sub>}<sub>2</sub>[1,2-di(4-pyridyl)ethylene], (I), is described which was isolated from the 1:1 reaction of Cd[S<sub>2</sub>CN(iPr)CH<sub>2</sub>CH<sub>2</sub>OH]<sub>2</sub> and 1,2-di(4-pyridyl)ethylene.

The crystallographic asymmetric unit of (I) contains half a molecule as the binuclear molecule/complex is located around a centre of inversion. As shown in the figure (70% displacement ellipsoids; unlabelled atoms are related by the symmetry operation (i)  $-x, 1 - y, 1 - z$ ), the Cd atom is

chelated by two dithiocarbamate ligands with the fifth position in the five-coordinate geometry completed by a N atom [Cd—N3 = 2.2879(13) Å] of the  $\mu_2$ -bridging 1,2-di(4-pyridyl) ethylene ligand. The dithiocarbamate ligands are coordinating in a symmetric mode [Cd—S1, S2 = 2.5603(4), 2.6676(4) Å and Cd—S3, S4 = 2.6009(4), 2.6280(4) Å] with the differences in the Cd—S bond lengths being small at 0.11 and 0.02 Å, respectively. This equivalence is reflected in the very narrow range in the associated C1—S1, S2 [1.7252(14), 1.7354(15) Å] and C7—S3, S4 [1.7284(15), 1.7291(15) Å] bond lengths. The angles subtended at the Cd atom range from a narrow 69.150(11) $^\circ$  for the S3—Cd—S4 chelate angle to a wide 155.796(12) $^\circ$  for S2—Cd—S4, i.e. subtended by the S atoms forming the weaker of the Cd—S bonds for each ligand. A measure of a five-coordination geometry is the value of  $\tau$  [13], which has values of 0.0 and 1.0 for ideal square-pyramidal and trigonal-pyramidal geometries, respectively. In (I),  $\tau$  = 0.10, being indicative of a square-pyramidal geometry. In this description, the Cd atom lies 0.5982(2) Å out of the S1—S4 plane [r.m.s. deviation = 0.0610 Å] in the direction of the N3 atom.

The crystal of (I) features conventional hydroxyl—O—H $\cdots$ O(hydroxyl) hydrogen bonding [O2—H<sub>2</sub>O $\cdots$ O1<sup>ii</sup>: H<sub>2</sub>O $\cdots$ O1<sup>ii</sup> = 1.959(19) Å, O2 $\cdots$ O1<sup>ii</sup> = 2.7879(18) Å with angle at H<sub>2</sub>O = 170.9(18) $^\circ$  for (ii)  $-1+x, 1+y, z$ ] as well as hydroxyl—O—H $\cdots$ S(thiolate) hydrogen bonds [O1—H1O $\cdots$ S2<sup>iii</sup>: H1O $\cdots$ S2<sup>iii</sup> = 2.455(18) Å, O1 $\cdots$ S2<sup>iii</sup> = 3.2775(12) Å with angle at H1O = 168.5(17) $^\circ$  for (iii)  $1+x, 1+y, z$ ], consistent with the notion that O—H $\cdots$ O hydrogen bonding is not all-pervasive and can be readily subjugated in hydroxyethyl-substituted dithiocarbamates [14]. In the present case, the aforementioned hydrogen bonding gives rise to a supramolecular layer in the *ab*-plane. The isopropyl substituents project to either side of the layers which stack along the *c*-axis direction. The directional interactions between layers appear to be methine-C—H $\cdots$ S(thiolate) [C4—H4 $\cdots$ S3<sup>iv</sup>: H4 $\cdots$ S3<sup>iv</sup> = 2.82 Å, C4 $\cdots$ S3<sup>iv</sup> = 3.5786(16) Å, with angle at H4 = 133 $^\circ$  for (iv)  $1-x, -1/2+y, 1/2-z$ ] and methyl-C—H $\cdots$  $\pi$ (chelate ring) [C5—H5c $\cdots$ Cg(Cd,S3,S4,C7)<sup>v</sup>: H5c $\cdots$ Cg(Cd,S3,S4,C7)<sup>v</sup> = 2.82 Å with angle at H5c = 127 $^\circ$  for (v)  $2-x, -1/2+y, 1/2-z$ ] interactions, the latter increasingly being recognised as important in the supramolecular chemistry of metal dithiocarbamates [15].

Finally, the Hirshfeld surfaces and two-dimensional fingerprint plots were calculated for (I) employing Crystal Explorer 17 [16] and literature methods [17]. The most prominent feature of the fingerprint plot is the appearance of sharp spikes ascribed to the O—H $\cdots$ O hydrogen bonding. Nevertheless, the total contribution to the overall Hirshfeld surface from H $\cdots$ O/O $\cdots$ H contacts is only 5.9%. Reflecting the significant role of S $\cdots$ H contacts in the molecular packing, in both the intra- and inter-layer regions, H $\cdots$ S/S $\cdots$ H contacts

amount to nearly a quarter of all contacts, i.e. 22.1%. The most significant contribution to the surface is due to H $\cdots$ H contacts, at 53.6%, with other notable contributions from H $\cdots$ C/C $\cdots$ C [8.5%] and S $\cdots$ C/C $\cdots$ S [3.5%] contacts.
